

# Discrete Data Graphs and Graph Neural Networks

October 23

Yale

#### A rare lull

- Assignment 3 out; due next Wednesday
- Assignment 4 posted next week
- Midterm scores and mid-semester grades posted tomorrow

## For today

- Quick recap
- Graphs for discrete data
- Intro to graph neural networks

## Graphs

- A natural language for describing various data
- Give information about relationships between variables
- Associated with each multivariate distribution

#### **Undirected Graphs**

A graph G = (V, E) has vertices V, edges E.

If  $X = (X_1, \dots, X_p)$  is a random variable, we will study graphs where there are p vertices, one for each  $X_i$ .

The graph will encode conditional independence relations among the variables.

## **Undirected graphs**

Simplest case:

Here 
$$V = \{X, Y, Z\}$$
 and  $E = \{(X, Y), (Y, Z)\}.$ 

This encodes the independence relation

$$X \perp \!\!\!\perp Z \mid Y$$

which means that *X* and *Z* are independent conditioned on *Y*.

#### **Markov Property**

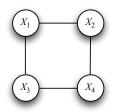

A probability distribution *P* satisfies the *global Markov property* with respect to a graph *G* if:

for any disjoint vertex subsets A, B, and C such that C separates A and B,

$$X_A \perp \!\!\!\perp X_B \mid X_C$$
.

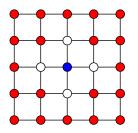

- $X_A$  are the random variables  $X_j$  with  $j \in A$ .
- C separates A and B means that there is no path from A to B that does not pass through C.

#### **Example**

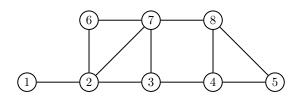

## **Example: 2-dimensional grid**

The blue node is independent of the red nodes given the white nodes.

#### **Example**

$$C=\{3,7\}$$
 separates  $A=\{1,2\}$  and  $B=\{4,8\}$ . Hence, 
$$\{X_1,X_2\} \perp\!\!\!\perp \{X_4,X_8\} \quad \big| \quad \{X_3,X_7\}$$

## Special case

If 
$$(i,j) \notin E$$
 then

$$X_i \perp \!\!\!\perp X_j \mid \{X_k : k \neq i, j\}$$

$$A = \{i\}, B = \{j\}, C = \{k \neq i, j\}$$

## Special case

If 
$$(i,j) \notin E$$
 then

$$X_i \perp \!\!\!\perp X_j \mid \{X_k : k \neq i, j\}$$

$$A = \{i\}, B = \{j\}, C = \{k \neq i, j\}$$

Lack of an edge from i to j implies that  $X_i$  and  $X_j$  are independent given all of the other random variables.

#### **Graph estimation**

- A graph G represents the class of distributions,  $\mathcal{P}(G)$ , the distributions that are Markov with respect to G
- Graph estimation: Given *n* samples  $X_1, \ldots, X_n \sim P$ , estimate the graph *G*.

#### **Factored form**

#### Theorem (Hammersley, Clifford, Besag)

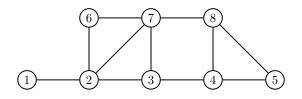

A positive distribution over random variables  $X_1, \ldots, X_p$  satisfies the Markov properties of graph G if and only if it can be represented as

$$p(X) \propto \prod_{c \in \mathcal{C}} \psi_c(X_c)$$

where C is the set of cliques in the graph G.

A clique is a subset of vertices for which each pair is connected by an edge.

#### **Example**

$$P(X) \propto \psi_{12}(X_1, X_2) \cdot \psi_{267}(X_2, X_6, X_7) \cdot \psi_{237}(X_2, X_3, X_7) \cdot \psi_{34}(X_3, X_4) \cdot \psi_{48}(X_4, X_8) \cdot \psi_{78}(X_7, X_8) \cdot \psi_{458}(X_4, X_5, X_8)$$

#### Gaussian case

Let  $\Omega = \Sigma^{-1}$  be the precision matrix.

A zero in  $\Omega$  indicates a *lack of the corresponding edge* in the graph

So, the adjacency matrix of the graph is

$$A = (\mathbb{1}(\Omega_{ij} \neq 0))$$

That is,

$$A_{ij} = egin{cases} 1 & ext{if } |\Omega_{ij}| > 0 \ 0 & ext{otherwise} \end{cases}$$

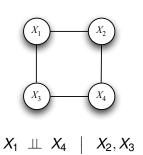

#### Gaussian case

$$\Omega \equiv \Sigma^{-1} = \begin{pmatrix} * & * & 0 \\ * & * & * \\ 0 & * & * \end{pmatrix}$$

#### Gaussian case

$$\Omega \equiv \Sigma^{-1} = egin{pmatrix} * & * & * & 0 \ * & * & 0 & * \ * & 0 & * & * \ 0 & * & * & * \end{pmatrix}$$

## **Gaussian case: Algorithms**

#### Two approaches:

- parallel lasso
- graphical lasso

#### Parallel Lasso:

- **1** For each j = 1, ..., p (in parallel): Regress  $X_j$  on all other variables using the lasso.
- 2 Put an edge between  $X_i$  and  $X_j$  if each appears in the regression of the other.

#### **Graphical Lasso (glasso)**

- Assume a multivariate Gaussian model
- Subtract out the sample mean
- Minimize the negative log-likelihood of the data, subject to a constraint on the sum of the absolute values of the inverse covariance

## **Graphical Lasso (glasso)**

The glasso optimizes the parameters of  $\Omega = \Sigma^{-1}$  by minimizing:

$$\operatorname{trace}(\Omega \mathcal{S}_n) - \log |\Omega| + \lambda \sum_{j \neq k} |\Omega_{jk}|$$

where  $|\Omega|$  is the determinant and  $S_n$  is the sample covariance

$$S_n = \frac{1}{n} \sum_{i=1}^n x_i x_i^T$$

There is a blockwise gradient descent algorithm to minimize this, using iterative lassos

## New material for today begins here

## **Discrete Graphical Models**

#### Challenges of handling discrete data:

- Models don't have closed from; can't compute normalizing constant
- Need to use Gibbs sampling, variational inference
- No analogue of the graphical lasso

#### **Discrete Graphical Models**

Positive distributions can be represented by an exponential family,

$$p(X) \propto \exp\left(\sum_{c \in \mathcal{C}} \phi_c(X_c)\right)$$

where  $\phi_c = \log \psi_c$  from Hammersley-Clifford

Special case: Ising Model (discrete Gaussian)

$$p_{eta}(X) \propto \exp\left(\sum_{i \in V} eta_i X_i + \sum_{(i,j) \in E} eta_{ij} X_i X_j
ight).$$

#### From edges to cliques

Take  $\beta_i \equiv 0$  for simplicity

If we have a triangle (i, j, k) in the graph then the potential function corresponds to

$$\psi_{ijk}(X_i, X_j, X_k) = e^{\beta_{ij}X_iX_j} \cdot e^{\beta_{jk}X_jX_k} \cdot e^{\beta_{ik}X_iX_k}$$
$$= e^{\beta_{ij}X_iX_j + \beta_{jk}X_jX_k + \beta_{ik}X_iX_k}$$

#### Ising

We have a graph with edges E and vertices V. Each node i has a random variable  $X_i$  that can be "up"  $(X_i = 1)$  or "down"  $(X_i = 0)$ 

$$p_{\beta}(x_1,\ldots,x_n) \propto \exp\left(\sum_{s\in V} \beta_s x_s + \sum_{(s,t)\in E} \beta_{st} x_s x_t\right)$$

Since  $2X_i - 1 \in \{-1, 1\}$  if  $X_i \in \{0, 1\}$ , can re-parameterize in terms of sample space  $X_i = \pm 1$ .

#### Ising

We have a graph with edges E and vertices V. Each node i has a random variable  $X_i$  that can be "up" ( $X_i = 1$ ) or "down" ( $X_i = 0$ )

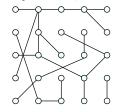

$$p_{\beta}(x_1,\ldots,x_n) \propto \exp\left(\sum_{s\in V} \beta_s x_s + \sum_{(s,t)\in E} \beta_{st} x_s x_t\right)$$

E are the set of edges, V are the vertices. Imagine the  $Z_i$  are votes of politicians, and the edges encode the social network of party affiliations

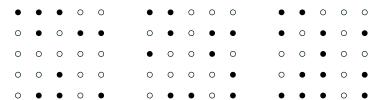

Since  $2X_i - 1 \in \{-1, 1\}$  if  $X_i \in \{0, 1\}$ , can re-parameterize in terms of sample space  $X_i = \pm 1$ .

#### **Graph Estimation**

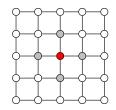

• Given n i.i.d. samples from an Ising distribution,  $\{X_i, i = 1, ..., n\}$ , (each is a p-vector of  $\{0, 1\}$  values) identify underlying graph

Multiple examples are observed:

#### **Local Distributions**

- Consider Ising model  $p_{\beta}(X) \propto \exp\left(\sum_{i \in V} \beta_i X_i + \sum_{(i,j) \in E} \beta_{ij} X_i X_j\right)$ .
- Conditioned on  $(x_2, \ldots, x_p)$ , variable  $X_1 \in \{0, 1\}$  has probability mass function given by a logistic function,

$$p(X_1 = 1 \mid x_2, ..., x_p) = \text{sigmoid} \left(\beta_1 + \sum_{j \in \mathcal{N}(1)} \beta_{1j} x_j\right)$$

## Parallel lasso (sparse logistic regressions)

#### **Strategy**

- Perform  $\ell_1$  regularized logistic regression of each node  $X_i$  on  $X_{i} = \{X_i, j \neq i\}$  to estimate neighbres  $\widehat{\mathcal{N}}(i)$
- Two versions:
  - ▶ Create an edge (i,j) if  $j \in \widehat{\mathcal{N}}(i)$  and  $i \in \widehat{\mathcal{N}}(j)$
  - ▶ Create an edge (i,j) if  $j \in \widehat{\mathcal{N}}(i)$  or  $i \in \widehat{\mathcal{N}}(j)$

## Parallel lasso (sparse logistic regressions)

## S&P 500: Ising Model (Price up or down?)

#### **Voting Data**

Voting records of US Senate, 2006-2008

Example of Banerjee, El Gahoui, and d'Asepremont

#### Scaling behavior: Performance with data size

Maximum degree d of the p variables. Sample size n must satisfy

Ising model:  $n \ge d^3 \log p$ 

Graphical lasso:  $n \ge d^2 \log p$ 

Parallel lasso:  $n \ge d \log p$ 

Lower bound:  $n \ge d \log p$ 

- Each method makes different incoherence assumptions:
  - Correlations between unrelated variables not too large

#### Summary: Graphs for discrete data

- A positive distribution factors into product of potential functions on the cliques of the graph
- Graphs and independence relations are same for discrete data
- Ising models are discrete Gaussians
- No version of the graphical lasso holds for discrete data; instead, we use the parallel lasso

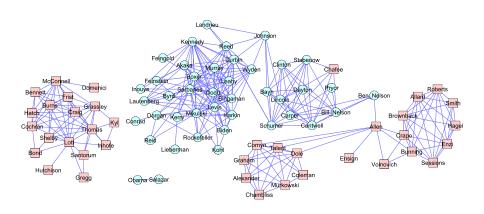

#### **Graph neural networks**

Next, we'll discuss graph neural networks, following this article:

https://distill.pub/2021/understanding-gnns/

#### **Recall: Voting Data**

Voting records of US Senate, 2006-2008

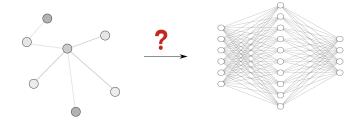

Suppose we have the graph and other covariates for each node or edge. How can we classify the senators according to political orientation?

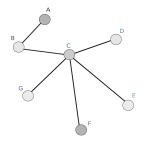

#### **Graph neural networks**

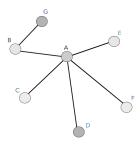

- We'll discuss how GNNs correspond to CNNs
- The graph Laplacian plays a central role

# **Equivariance problem**

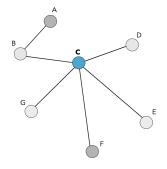

# **Equivariance problem**

#### **Graph Laplacian**

Input Graph 
$$G$$

Laplacian L of G

#### Polynomials of the Laplacian

$$p_w(L) = w_0 I_n + w_1 L + w_2 L^2 + \cdots + w_d L^d$$
  
If dist $(u, v) > i$  then the  $(u, v)$  entry of  $L^i$  is zero

- This is analogous to a CNN filter (kernel)
- The weights w<sub>i</sub> play role of filter coefficients
- Degree d of polynomial plays role of the size of the kernel

#### The Laplacian is a Mercer kernel

- Symmetric  $L_{uv} = L_{vu}$
- Positive-definite:

$$f^T L f = \sum_{(u,v) \in E} (f_u - f_v)^2 \ge 0$$

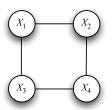

For more on properties of such kernels: https://www.ml.cmu.edu/research/dap-papers/kondor-diffusion-kernels.pdf, https://mlg.eng.cam.ac.uk/zoubin/papers/ssl-book.pdf

#### **Classical Laplacian**

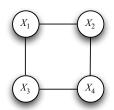

$$\Delta = \operatorname{trace}\left(\frac{\partial^2}{\partial x_i \partial x_j}\right) = \frac{\partial^2}{\partial x_1^2} + \dots + \frac{\partial^2}{\partial x_n^2}$$

The Laplace operator in its various manifestations is the most beautiful and central object in all of mathematics. Probability theory, mathematical physics, Fourier analysis, partial differential equations, the theory of Lie groups, and differential geometry all revolve around this sun, and its light even penetrates such obscure regions as number theory and algebraic geometry.

Edward Nelson, Tensor Analysis

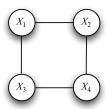

What is the Laplacian L?

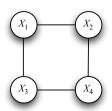

#### What is the Laplacian L?

$$L = \begin{pmatrix} 2 & -1 & -1 & 0 \\ -1 & 2 & 0 & -1 \\ -1 & 0 & 2 & -1 \\ 0 & -1 & -1 & 2 \end{pmatrix}$$

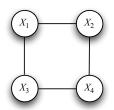

What is  $L^2$ ?

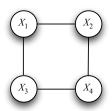

What is  $L^2$ ?

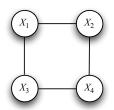

$$L^2 = \begin{pmatrix} 6 & -4 & -4 & 2 \\ -4 & 6 & 2 & -4 \\ -4 & 2 & 6 & -4 \\ 2 & -4 & -4 & 6 \end{pmatrix}$$

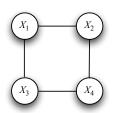

If  $x = (1, 2, 3, 4)^T$  what is h = ReLU(Lx)?

If 
$$x = (1, 2, 3, 4)^T$$
 what is  $h = \text{ReLU}(Lx)$ ?  
 $\text{ReLU}(Lx) = \text{ReLU}((-3, -1, 1, 3)^T) = (0, 0, 1, 3)^T$ 

If  $x = (1, 2, 3, 4)^T$  what is  $x^T L x$ ?

If 
$$x = (1, 2, 3, 4)^T$$
 what is  $x^T L x$ ?

$$x^T L x = \sum_{(u,v) \in E} (x_u - x_v)^2 = 10$$

#### **Equivariance**

If we compute a feature map f, we'd like it to not depend on a reordering P of the nodes.

#### The reordering

$$\mathbf{2} \leftarrow \mathbf{3}$$

$$\mathbf{3} \leftarrow \mathbf{1}$$

corresponds to permutation matrix

$$P = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}$$

## Whence equivariance

A transformation  $f: \mathbb{R}^n \longrightarrow \mathbb{R}^n$  is equivariant if

$$f(Px) = Pf(x)$$

for any permuation matrix P, where  $PP^T = I$ .

The transformed data and Laplacian are

$$\begin{aligned} x &\longrightarrow Px \\ L &\longrightarrow PLP^T \\ L^i &\longrightarrow PL^iP^T \end{aligned}$$

#### Whence equivariance

A transformation  $f: \mathbb{R}^n \longrightarrow \mathbb{R}^n$  is equivariant if

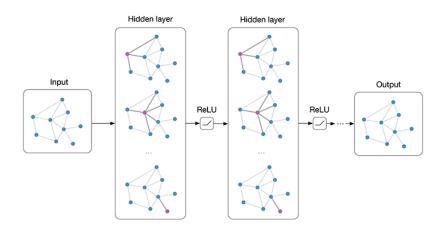

$$f(Px) = Pf(x)$$

for any permuation matrix P, where  $PP^T = I$ .

The transformed polynomial kernels are

$$f(Px) = \sum_{i=0}^{d} w_i (PL^i P^T) Px$$
$$= \sum_{i=0}^{d} w_i PL^i x$$
$$= P \sum_{i=0}^{d} w_i L^i x$$
$$= Pf(x)$$

#### **Building layers**

## **Building layers**

• In this example, the first layer gives three "feature maps"

$$h_1 = \text{relu}(p_{w_1}(L)x)$$
  
 $h_2 = \text{relu}(p_{w_2}(L)x)$   
 $h_3 = \text{relu}(p_{w_3}(L)x)$ 

The final output is then computed as

$$y = \text{relu}(\beta^T h)$$

• The hidden states  $h_i$  and output y are vectors, with a component for each node in the graph.

CPSC 483: Deep Learning on Graphs

Instructor: Rex Ying

#### **Summary: Graph neural nets**

- Certain data have natural graphical structure
- GNNs are analogues of CNNs for graphs
- Based on use of graph Laplacian
- Independent of ordering of nodes (equivariant)

#### A recent framework that combines ideas from CNNs and GNNs

# **Next topic: Reinforcement learning**
